## 1 Asymptotic Notation

```
Upper Bounds T(n) = O(f(n)) if exist constants c > 0 and n_0 \ge 0 such that for all n \ge n_0, T(n) \le c \cdot f(n). Lower Bounds T(n) = \Omega(f(n)) if exist constants c > 0 and n_0 \ge 0 such that for all n \ge n_0, T(n) \ge c \cdot f(n). Tight Bounds T(n) = \Theta(f(n)) if T(n) = O(f(n)) and T(n) = \Omega(f(n)). Note: Here "=" means "is", not equal.
```

## 2 Introduction - The Sorting Problem

#### 2.1 Selection Sort

```
Algorithm 1: Selection Sort

Input: An array A[1...n] of elements

Output: Array A[1...n] of elements in sorted order (asending)

for i \leftarrow 1 to n-1 do

for j \leftarrow i+1 to n do

if A[i] > A[j] then

| swap A[i] and A[j]

end

end

end
```

```
Running Time: \frac{n(n-1)}{2}
Best-Case = Worst-Case: T(n) = \Theta(\frac{n(n-1)}{2}) = \Theta(n^2)
```

## 2.2 Insertion Sort

```
Algorithm 2: Insertion Sort

Input: An array A[1...n] of elements

Output: Array A[1...n] of elements in sorted order (asending) for i \leftarrow 2 to n do

\begin{vmatrix}
j \leftarrow i - 1 \text{ while } j \ge 1 \text{ and } A[j] > A[j+1] \text{ do} \\
\text{swap } A[j] \text{ and } A[j+1] \\
\text{end} \\
\text{j} \leftarrow j - 1 \\
\text{end}
\end{vmatrix}
```

```
Running Time: Depends on the input array, ranges between (n-1) and \frac{n(n-1)}{2} Best-Case: T(n) = n-1 = \Theta(n) (Useless) Worst-Case: T(n) = \Theta(\frac{n(n-1)}{2}) = \Theta(n^2) (Commonly-Used) Average-Case: T(n) = \Theta(\sum_{i=2}^n \frac{i-1}{2}) = \Theta(\frac{n(n-1)}{4}) = \Theta(n^2) (Sometimes Used)
```

## 2.3 Wild-Guess Sort

Running Time: Depends on the random generation, could be faster than the insertion sort.

## 2.4 Worst-Case Analysis

The algorithm's worst case running time is  $O(f(n)) \implies On$  all inputs of (large) size n, the running time of the algorithm is  $\leq c \cdot f(n)$ .

## Algorithm 3: Wild-Guess Sort

**Input:** An array A[1...n] of elements

**Output:** Array A[1...n] of elements in sorted order (asending)

 $\pi \leftarrow [4,7,1,3,8,11,5,...]$  Create random permutation Check if  $A[\pi[i]] \leq A[\pi[i+1]]$  for all i=1,2,...,n-1 If yes, output A according to  $\pi$  and terminate else Insertion - Sort(A)

The algorithm's worst case running time is  $\Omega(f(n)) \Longrightarrow$  There exists at least one input of (large) size n for which the running time of the algorithm is  $\geq c \cdot f(n)$ .

Thus, Insertion sort runs in  $\Theta(n^2)$  time.

## Notice

Selection sort, insertion sort, and wild-guess sort all have worst-case running time  $\Theta(n^2)$ . How to distinguish between them?

- Closer examination of hidden constants
- Careful analysis of typical expected inputs
- Other factors such as cache efficiency, parallelization are important
- Empirical comparison

## Stirling's Formula

Prove that  $\log(n!) = \Theta(n \log n)$ 

First  $\log(n!) = O(n \log n)$  since:

$$\log(n!) = \sum_{i=1}^{n} \log i \le n \times \log n = O(n \log n)$$

Second  $\log(n!) = \Omega(n \log n)$  since:

$$\log(n!) = \sum_{i=1}^{n} \log i \ge \sum_{i=n/2}^{n} \log i \ge n/2 \times \log n/2 = n/2(\log n - \log 2) = \Omega(n \log n)$$

Thus,  $\log(n!) = \Theta(n \log n)$ 

## 3 Divide & Conquer

Main idea of D & C: Solve a problem of size n by breaking it into one or more smaller problems of size less than n. Solve the smaller problems recursively and combine their solutions, to solve the large problem.

## 3.1 Binary Search

```
Example: Binary Search
Input: A sorted array A[1,...,n], and an element x
Output: Return the position of x, if it is in A; otherwise output nil
Idea of the binary search: Set q \leftarrow middle of the array. If x = A[q], return q. If x < A[q], search A[1,...,q-1], else search A[q+1,...,n].
```

## Algorithm 4: Binary Search

```
Input: Array A[1...n] of elements in sorted order

BinarySearch(A[],p,r,x)(p,r) being the left & right iteration, x being the element being searched)

if p > r then

| return nil
end

q \leftarrow [(p+r)/2]
if x = A[q] then

| return q
end
if x < A[q] then

| BinarySearch(A[],p,q-1,x)
end
else

| BinarySearch(A[],q+1,r,x)
end
```

```
Recurrence of the algorithm, supposing T(n) being the number of the comparisons needed for n elements: T(n) = T(\frac{n}{2}) + 2 if n > 1, with T(1) = 2. \implies T(n) = 2 \log_2 n + 2 \implies O(\log n) algorithm
```

## Example: Binary Search in Rotated Array

Suppose you are given a sorted array A of n distinct numbers that has been rotated k steps, for some unknown integer k between 1 and n-1. That is, A[1...k] is sorted in increasing order, and A[k+1...n] is also sorted in increasing order, and A[n] < A[1].

Design an  $O(\log n)$ -time algorithm that for any given x, finds x in the rotated sorted array, or reports that it does not exist.

### Algorithm:

First conduct a  $O(\log n)$  algorithm to find the value of k, then search for the target value in either the first part or the second part.

```
Find - x(A, x)
k \leftarrow Find - k(A, 1, n) \text{ (First find } k)
if \ x \ge A[1] \ then \ return \ BinarySearch(A, 1, k, x)
Else \ return \ BinarySearch(A, k + 1, n, x)
```

## Example: Finding the last 0

You are given an array A[1...n] that contains a sequence of 0 followed by a sequence of 1 (e.g., 0001111111). A contains k 0(s) (k > 0 and k << n) and at least one 1.

Design an  $O(\log k)$ -time algorithm that finds the position k of the last 0.

#### Algorithm:

```
\begin{aligned} i \leftarrow 1 \\ while \ A[i] &= 0 \\ i \leftarrow 2i \\ find - k(A[i/2...i]) \end{aligned}
```

## 3.2 Merge Sort

## Principle of the Merge Sort:

- Divide array into two halves.
- Recursively sort each half.
- Merge two halves to make sorted whole.

## Algorithm 5: Merge Sort

```
MergeSort (A, p, r) (p, r) being the left & right side of the array to be sorted) if p = r then | return end q \leftarrow [(p+r)/2] MergeSort (A, p, q) MergeSort (A, p, q, r) First Call: MergeSort (A, 1, n)
```

## Algorithm 6: Merge

```
Input: Two Arrays L \leftarrow A[p...q] and R \leftarrow A[q+1...r] of elements in sorted order Merge (A, p, q, r) Append \infty at the end of L and R i \leftarrow 1, \ j \leftarrow 1 for k \leftarrow p to r do if L[i] \leq R[j] then A[k] \leftarrow L[i] i \leftarrow i+1 end else A[k] \leftarrow R[j] j \leftarrow j+1 end end end
```

Let T(n) be the running time of the algorithm on an array of size n.

### Merge Sort Recurrence:

$$T(n) \le T(\lfloor n/2 \rfloor) + T(\lceil n/2 \rceil) + O(n), \quad n > 1, \quad T(1) = O(1)$$

Simplification:

$$\implies T(n) = 2T(n/2) + n, \quad n > 1, \quad T(1) = 1$$

Result:

$$T(n) = n \log_2 n + n = O(n \log n)$$

## 3.3 Inversion Counting

**Definition of the Inversion Numbers:** Given array A[1...n], two elements A[i] and A[j] are inverted if i < j but A[i] > A[j]. The inversion number of A is the number of inverted pairs.

#### Theorem:

The number of swaps used by Insertion Sort = Inversion Number (Proved by induction on the size of the array)

## Algorithm to Compute Inversion Number:

Algorithm 1: Check all  $\Theta(n^2)$  pairs.

Algorithm 2: Run Insertion Sort and count the number of swaps -Also  $\Theta(n^2)$  time.

Algorithm 3: Divide and Conquer

## 3.3.1 Counting Inversions: Divide-and-Conquer

## Principle of the Algorithm:

- Divide: divide array into two halves
- Conquer: recursively count inversions in each half
- $\bullet$  Conbine: count inversions where  $a_i$  and  $a_j$  are in different halves, and return sum of three quantities

Inversion counting during the combine step is very similar to the Merge Algorithm (Algorithm 6), by counting the sum of each inversion number of the right array (indicated by I[j]) comparing to the left array.

## Algorithm 7: Inversion Count during Combination

```
Input: Two Arrays L \leftarrow A[p...q] and R \leftarrow A[q+1...r] of elements in sorted order Count (A, p, q, r) i \leftarrow 1, \ j \leftarrow 1, \ c \leftarrow 0 while (i \leq q-p+1)\&\&(j \leq r-q) do if L[i] \leq R[j] then |i \leftarrow i+1| end else |I[j] = q-p-i+2| c \leftarrow c+I[j] j \leftarrow j+1 end end
```

The time-complexity of the algorithm is  $\Theta(n \log n)$ , same as the Merge Sort.

#### 3.3.2 Implementation of the Algorithm

#### Algorithm 8: Main Algorithm

```
\begin{array}{l} \operatorname{Sort-and-Count}(A,p,r) \\ \text{if } p = r \text{ then} \\ \mid \text{ return } \theta \\ \text{end} \\ q \leftarrow \lfloor (p+r)/2 \rfloor \\ c_1 \leftarrow \operatorname{Sort-and-Count}(A,p,q) \\ c_2 \leftarrow \operatorname{Sort-and-Count}(A,q+1,r) \\ c_3 \leftarrow \operatorname{Merge-and-Count}(A,p,q,r) \\ \text{return } c_1 + c_2 + c_3 \\ \underline{\operatorname{First Call:}} \operatorname{Sort-and-Count}(A,1,n) \end{array}
```

#### Algorithm 9: Merge-and-Count

```
Input: Two Arrays L \leftarrow A[p...q] and R \leftarrow A[q+1...r] of elements in sorted order
Merge-and-Count (A, p, q, r)
Append \infty at the end of L and R
i \leftarrow 1, j \leftarrow 1, c \leftarrow 0
for k \leftarrow p to r do
    if L[i] \leq R[j] then
         A[k] \leftarrow L[i]
        i \leftarrow i + 1
    end
    else
         A[k] \leftarrow R[j]
         j \leftarrow j+1
        c \leftarrow c + q - p - i + 2
    end
end
return c
```

## 3.4 Basic Summary of D&C: Problem Size & Number of Problems

## Observations of D&C in Logarithmic Patterns:

- Break up problem of size n into p parts of size n/q.
- Solve parts recursively and combine solutions into overall solution.
- At level i, we break i times and we have  $p^i$  problems of size  $n/q^i$ .
- When we cannot break up any more, usually when the problem size becomes 1. Usually  $i \approx \log_a n$ .

```
The number of problems at (bottom) level \log_q n is p^i = p^{\log_q n} = n^{\log_q p}.
```

## Observations of D&C in Non-Logarithmic Patterns:

- Break up problem of size n into  $p(\leq 2)$  parts of size n-q. (e.g. q=1 for Hanoi Problem)
- Assume that q = 1
- At level i, we break i times and we have  $p^i$  problems of size n-i.
- If we stop when the problem size becomes 1, then  $n-i=1 \implies i=n-1$ .

The number of problems at (bottom) level n-1 is:  $p^i = p^{n-1}$ .

## 3.5 Maximum Contiguous Subarray

```
Example: The Maximum Subarray Problem Input: An array of numbers A[1,...,n], both positive and negative Output: Find the maximum V(i,j), where V(i,j) = \sum_{k=i}^{j} A[k]
```

### Brute-Force Algorithm

**Idea:** Calculate the value of V(i, j) for each pair  $i \leq j$  and return the maximum value. Requires three nested for-loop, time complexity:  $\Theta(n^3)$ .

#### A Data-Reuse Algorithm

```
Idea: V(i, j) = V(i, j - 1) + A[j]
Requires two nested for-loop, time complexity: \Theta(n^2).
```

#### 3.5.1 A D&C Algorithm

Idea: Cut the array into two halves, all subarrays can be classified into three cases: entirely in the first/second half, or crosses the cut.

Compare with the merge sort: Whole algorithm will run in  $\Theta(n \log n)$  time if the cross-cut can be solved in O(n) time.

#### Algorithm 10: Maximum Subarray

```
MaxSubArray(A, p, r)
if p = r then
 return A[p]
end
q \leftarrow \lfloor (p+r)/2 \rfloor
M_1 \leftarrow \texttt{MaxSubArray}(A, p, q)
M_2 \leftarrow \texttt{MaxSubArray}(A, q+1, r)
L_m, R_m \leftarrow -\infty
V \leftarrow 0
for i \leftarrow q \ to \ p \ \mathbf{do}
      V \leftarrow V + A[i]
     \mathbf{if}\ V > L_{m_{-}}\mathbf{then}
      \mid L_m \leftarrow V
      end
end
V \leftarrow 0
for i \leftarrow q + 1 to r do
     V \leftarrow V + A[i]
     \begin{array}{ccc} \textbf{if} \ V > R_m \ \textbf{then} \\ | \ R_m \leftarrow V \end{array}
      end
end
return \max(M_1, M_2, L_m + R_m)
First Call: MaxSubArray (A, 1, n)
```

**Recurrence:**  $T(n) = 2T(n/2) + n \implies T(n) = \Theta(n \log n)$ 

#### 3.5.2 Kadane's Algorithm

**Idea:** Based on the principles of **Dynamic Programming**. Let V[i] be the (local) maximum sub-array that ends at A[i], then we let:

```
\bullet V[1] = A[1]

\bullet V[i] = \max(A[i], A[i] + V[i-1])
```

The maximum of V[i], namely  $V_{max}$  is the maximum continuous subarray found so far.

## Algorithm 11: Kadane's Algorithm

## **Example: Maximizing Stock Profits**

You are presented with an array  $p[1 \dots n]$  where p[i] is the price of the stock on day i.

Design an divide-and-conquer algorithm that finds a strategy to make as much money as possible, i.e., it finds a pair i, j with  $1 \le i \le j \le n$  such that p[j] - p[i] is maximized over all possible such pairs. Note that you are only allowed to buy the stock once and then sell it later.

## Idea 1: Divide and Conquer

- Cut the array into two halves.
- All i, j solutions can be classified into three cases: both i, j are entirely in the first(second) half, or i is in the left half while j is in the right half.
- Maximizing a Case 3 result p[j] p[i] means finding the smallest value in the first half and the largest in the second half.

Time Complexity:  $T(n) = 2T(n/2) + n \implies T(n) = \Theta(n \log n)$ 

## Idea 2: Kadane's Algorithm

- Create a **Profit** array with Profit[i] = Price[i+1] Price[i].
- Perform the Kadane's Algorithm.

Time Complexity: O(n)

## 3.6 Integer and Matrix Multiplication

## 3.6.1 A Simple D&C Algorithm for Integer Multiplication

**Goal:** Given two *n*-bit binary integers a and b, compute:  $a \cdot b$ .

**Idea:** Multiplication by  $2^k$  can be done in one time unit by a left shift of k bits.

- Rewrite the two numbers as  $a = 2^{n/2}a_1 + a_0$ ,  $b = 2^{n/2}b_1 + b_0$ .
- $\bullet \text{ The product becomes: } a \cdot b = (2^{n/2}a_1 + a_0)(2^{n/2}b_1 + b_0) = 2^na_1b_1 + 2^{n/2}(a_1b_0 + a_0b_1) + a_0b_0$
- The new computation requires 4 products of integers, each with n/2 bits.
- Apply D&C by splitting a problem of size n, to 4 problems of size n/2.

## Algorithm 12: Binary Multiplication

```
\begin{split} &\text{Multiply}(A,B) \\ &n \leftarrow \text{size of } A \\ &\textbf{if } n = 1 \textbf{ then} \\ &| \textbf{ return } A[1] \cdot B[1] \\ &\textbf{end} \\ &mid \leftarrow \lfloor n/2 \rfloor \\ &U \leftarrow \texttt{Multiply } (A[mid+1..n], B[mid+1..n]) \; / / \; a_1b_1 \\ &V \leftarrow \texttt{Multiply } (A[mid+1..n], B[1..mid]) \; / / \; a_0b_0 \\ &W \leftarrow \texttt{Multiply } (A[1..mid], B[mid+1..n]) \; / / \; a_0b_1 \\ &Z \leftarrow \texttt{Multiply } (A[1..mid], B[1..mid]) \; / / \; a_0b_0 \\ &M[1..2n] \leftarrow 0 \\ &M[1..2n] \leftarrow 0 \\ &M[1..n] \leftarrow Z \; / / \; a_0b_0 \\ &M[mid+1..] \leftarrow M[mid+1..] \oplus V \oplus W \; / / \; + [(a_1b_0+a_0b_1) \ll (\text{left shift) } n/2] \\ &M[2mid+1..] \leftarrow M[2mid+1..] \oplus U \; / / \; + [a_1b_1 \ll n] \\ &\textbf{return } M \end{split}
```

Time Complexity:  $T(n) = 4T(n/2) + n \implies T(n) = \Theta(n^2)$ 

## 3.6.2 Karatsuba Multiplication

**Goal:** Given two *n*-bit binary integers a and b, compute:  $a \cdot b$ .

- We've seen that  $ab = a_1b_12^n + (a_1b_0 + a_0b_1)2^{n/2} + a_0b_0$ , so we only need the result of  $a_1b_0 + a_0b_1$ .
- Note that  $a_1b_0 + a_0b_1 = (a_1 + a_0)(b_1 + b_0) a_1b_1 a_0b_0$ , thus only requires performing 3 multiplications of size n/2.

## Algorithm 13: Binary Multiplication (Karatsuba's Multiplication Algorithm)

```
Multiply(A, B)
n \leftarrow \text{size of } A
if n = 1 then
 | return A[1] \cdot B[1]
end
mid \leftarrow \lfloor n/2 \rfloor
U \leftarrow \text{Multiply } (A[mid + 1..n], B[mid + 1..n]) // a_1b_1
Z \leftarrow \texttt{Multiply} \ (A[1..mid], B[1..mid]) \ // \ a_0b_0
A' \leftarrow A[mid + 1..n] \oplus A[1..mid] // a_1 + a_0
B' \leftarrow B[mid + 1..n] \oplus B[1..mid] // b_1 + b_0
Y \leftarrow \text{Multiply } (A', B') // (a_1 + a_0)(b_! + b_0)
M[1..2n] \leftarrow 0
M[1..n] \leftarrow Z // a_0 b_0
M[mid+1..] \leftarrow M[mid+1..] \oplus Y \ominus U \ominus Z // + [(a_1b_0 + a_0b_1) \ll (left shift) n/2]
M[2mid + 1..] \leftarrow M[2mid + 1..] \oplus U // + [a_1b_1 \ll n]
return M
```

Time Complexity:  $T(n) = 3T(n/2) + n \implies T(n) = \Theta(n^{\log_2 3}) = \Theta(n^{1.585\cdots})$ For recent research, see: Integer Multiplication in  $O(n \log n)$  Time (David Harvey & Joris van der Hoeven, 2021)

## 3.7 Matrix Multiplication

$$\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ c_{n1} & c_{n2} & \cdots & c_{nn} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1n} \\ b_{21} & b_{22} & \cdots & b_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ b_{n1} & b_{n2} & \cdots & b_{nn} \end{bmatrix} \quad c_{ij} = \sum_{k=1}^{n} a_{ik} b_{kj}$$

Brute Force Method:  $\Theta(n^3)$  time.

#### 3.7.1 A D&C Solution to Matrix Multiplication

$$\begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \quad \begin{cases} C_{11} = (A_{11} \times B_{11}) + (A_{12} \times B_{21}) \\ C_{12} = (A_{11} \times B_{12}) + (A_{12} \times B_{22}) \\ C_{21} = (A_{21} \times B_{11}) + (A_{22} \times B_{21}) \\ C_{22} = (A_{21} \times B_{12}) + (A_{22} \times B_{22}) \end{cases}$$

**Recursion:**  $T(n) = 8T(n/2) + O(n^2) \implies T(n) = O(n^3)$ 

## 3.7.2 Strassen's Matrix Multiplication Algorithm

**Idea:** Muliply 2-by-2 block matrices with only 7 multiplications

$$\begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$
 
$$\begin{cases} P_1 = A_{11} \times (B_{12} - B_{22}) \\ P_2 = (A_{11} + A_{12}) \times B_{22} \\ P_3 = (A_{21} + A_{22}) \times B_{11} \\ P_4 = A_{22} \times (B_{21} - B_{11}) \\ P_5 = (A_{11} + A_{12}) \times (B_{11} + B_{22}) \\ P_6 = (A_{12} - A_{22}) \times (B_{21} + B_{22}) \\ P_7 = (A_{11} - A_{21}) \times (B_{11} + B_{12}) \end{cases}$$
 
$$\begin{cases} C_{11} = P_5 + P_4 - P_2 + P_6 \\ C_{12} = P_1 + P_2 \\ C_{21} = P_3 + P_4 \\ C_{22} = P_5 + P_1 - P_3 - P_7 \end{cases}$$

Recursion:  $T(n) = 7T(n/2) + n^2 \implies T(n) = \Theta(n^{\log_2 7}) = \Theta(n^{2.807\cdots})$ 

For recent research, see: Powers of Tensors and Fast Matrix Multiplication (Le Gall, 2014)

Conjecture: Close to  $\Theta(n^2)$ 

## 3.8 Master Theorem

For recurrences of form

$$T(n) = aT(n/b) + f(n)$$
 or  $T(n) \le aT(n/b) + f(n)$ , Let  $c \equiv \log_b a$ 

where

- $a \ge 1$  and b > 1 both being constants
- f(n) is a (asymptotically) positive polynomial function
- n/b could be either  $\lfloor n/b \rfloor$  or  $\lceil n/b \rceil$

#### 3.8.1 Master Theorem for Equalities

- (1) Work Increases:  $f(n) = O(n^{c-\epsilon})$  for some  $\epsilon \implies T(n) = \Theta(n^c)$
- (2) Work Remains:  $f(n) = \Theta(n^c \log^k n)$  for  $k > -1 \implies T(n) = \Theta(n^c \log^{k+1} n)$ Note: For the case k = -1,  $T(n) = \Theta(n^c \log \log n)$ ; For the case k < -1,  $T(n) = \Theta(n^c)$
- (3) Work Decreases:  $f(n) = \Omega(n^{c+\epsilon})$  for some  $\epsilon \implies T(n) = \Theta(f(n))$ Note: Rigorously, the third case requires  $af(n/b) \le kf(n)$  for some k < 1 and sufficiently large n
- (4) For a special case  $T(n) = \sum_i T(\alpha_i n) + n$  where  $\alpha_i > 0$  with  $\sum_i \alpha_i < 1$ , we have  $T(n) = \Theta(n)$

## 3.8.2 Master Theorem for Inequalities

- (1) Work Increases:  $f(n) = O(n^{c-\epsilon})$  for some  $\epsilon \implies T(n) = O(n^c)$
- (2) Work Remains:  $f(n) = O(n^c) \implies T(n) = O(n^c \log n)$
- (3) Work Decreases:  $f(n) = \Omega(n^{c+\epsilon})$  for some  $\epsilon \implies T(n) = O(f(n))$

## 4 Basic Randomized Algorithms

## 4.1 Probability & Statistics

$$E[X] = \sum i \cdot Pr[X = i]$$

$$E[X+Y] = E[X] + E[Y]$$

For independent random variables X & Y,

$$E[XY] = E[X] \cdot E[Y]$$

#### 4.2 Generate a Random Permutation

## Algorithm 14: Random Permutation

```
\begin{split} & \operatorname{RandomPermute}(A) \\ & n \leftarrow A.length \\ & \mathbf{for} \ i \leftarrow 1 \ to \ n \ \mathbf{do} \\ & | \ \operatorname{swap} \ A[i] \ \text{with} \ A[Random(1,i)] \\ & \mathbf{end} \end{split}
```

## 4.3 Quick Sort

**Idea:** Quicksort chooses item as pivot. It partitions array so that all items less than or equal to pivot are on the left and all items greater than pivot on the right. It then recursively Quicksorts left and right sides.

## Algorithm 15: Quick Sort

```
Quicksort (A, p, r) // Array from A[p] to A[r]
if p \ge r then
 return
end
q = \text{Partition}(A, p, r) // \text{Set a new pivot position}
Quicksort (A, p, q - 1)
Quicksort (A, q + 1, r)
First Call: MaxSubArray(A, 1, n)
Partition (A, p, r)
x \leftarrow A[r] // Set the last item as pivot, or randomly swap away the last item before choosing the pivot
i \leftarrow p-1
for j \leftarrow p \ to \ r-1 \ \mathbf{do}
   if A[j] \leq x then
       swap A[i] and A[j] // Put all items \leq A[r] on the left
   end
end
swap A[i+1] and A[r]
return i+1
```

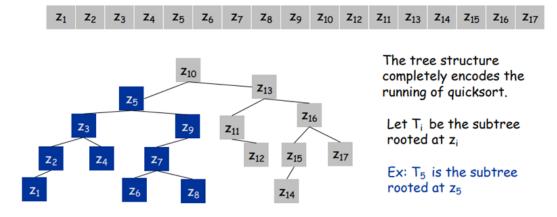

## 4.3.1 Running Time

Best Case: Always select the median element as the pivot -  $\Theta(n \log n)$  time.

Worst Case: Always select the smallest (or the largest) element -  $\Theta(n^2)$  time.

To make running time independent of input, we can randomly choose an element as the pivot by swapping it with last item in array before running the partition.

## 4.3.2 Binary Tree Representation

This means that when  $z_i$  was a pivot, its subarray contained exactly the items in  $T_i$ 

Those items are then partitioned around  $z_i$  (corresponding to being placed in the left and right subtrees).

#### Fact

- (\*) z<sub>i</sub> is compared with z<sub>j</sub> by Qsort if and only if
- (\*\*) in the tree
  - $z_i$  is an ancestor of  $z_j$
  - or  $z_i$  is an ancestor of  $z_i$

#### 4.3.3 Expected Running Time for Random-Based Quick Sort

- Two elements  $z_i$  and  $z_j$  are compared at most once, iff  $z_i$  or  $z_j$  is the first to be chosen among  $z_i, \dots, z_j$
- The probability above (any indicated two elements  $z_i$  and  $z_j$  are compared) is  $\frac{2}{j-1+1}$

$$\implies E_{\text{Num of comparisons made}} = \sum_{i < j} \frac{2}{j-1+1} = O(n \log n)$$
